Current scenario of urolithiasis and the use of medicinal plants as antiurolithiatic agents in Manipur (North East India): A Review

Khaling Mikawlrawng, Suresh Kumar, Vandana

ABSTRACT

Almost every family in Manipur has a member afflicted with urolithiasis. Standard pharmaceutical drugs used to prevent and cure urolithiasis are not effective in all cases, costly, quite common recurrences, risks of long term fertility, potential side effects and no guarantee. Despite the improvements in medical techniques such as extracorporeal shock wave lithotripsy and percutaneous nephrolithotomy, the worldwide incidence of urolithiasis is quite high and there is no truly satisfactory drug for treatment of renal calculi. A large number of Indian medicinal plants have been used in the treatment of urolithiasis and they have been reported to be effective with fewer side effects. This paper deals with the current scenario of Urolithiasis in Manipur and reported the detail documentations of 107 plants from Manipur currently used by different ethnic communities as antiurolithiatic agents.

Keywords: Urolithiasis, Manipur, Biodiversity Hot spots, medicinal plants.

1. Introduction

Urolithiasis, which is referred to as the process of formation of calculi (singular calculus) in the urinary system includes Nephrolithiasis (Renal Calculi or Kidney Stones), Ureterolithiasis (Ureter Calculi) and Cystolithiasis (Bladder Calculi). Urinary stones are one of the major problems and an important cause of morbidity and end stage renal failure in India. Stone formation is one of the painful urologic disorders that occur in approximately 12% of the global population, and its recurrence rate in males is 70-81% in males and 47-60% in females [1]. These calculi (stones) create problems by blocking the flow of urine and cause severe pain termed as renal colic when they move along the ureter. Urolithiasis can also be associated with morbidity and renal damage. The disease affects all age groups from less than 1 year old to more than 70 years [2]. After their initial stone episode the recurrence rate of stone is approximately 10% within one year, 35% within five years, and 50% within 10 years [3].

1.1 Prevalence of Urolithiasis

Primary stone formation and recurrence of stone formation is one of the biggest challenges faced by urologists today and remain a major source of morbidity in humans [4]. The peak age for onset of stone formation is in the third decade, and prevalence increases with age until 70. During the past few decades, the prevalence of kidney stones in both males and females has markedly increased in industrialized countries. This is presumably due to changes in lifestyle and dietary habit of the people in these regions [5]. The increased incidence of urinary stones in the industrialized world is associated with improved standards of living (mainly including the high dietary intake of proteins and minerals) [6]. Kidney stone incidence varies in different parts of the world, high incidence areas are Scandinavian countries, Mediterranean countries, British Isles, northern Australia, central Europe, portions of the Malayan Peninsula, China, Pakistan and northern India whereas the incidence of kidney stone formation is lower in areas like Central and South America, some parts of Africa. In Asia stone-forming belt has been reported to stretch across Sudan, Saudi Arabia, the United Arab Emirates, the Islamic Republic of Iran, Pakistan, India, Myanmar, Thailand, Indonesia and Philippines. In India, the “stone belt” occupies some parts of Maharashtra, Gujarat, Punjab, Haryana, Delhi and Rajasthan [7]. The effect of geography on the incidence of stone formation may be direct, through its effect on temperature; high temperatures increase perspiration, which may result in concentrated urine, which in turn promotes increased urinary crystallization.
In general, urolithiasis affects all age groups from less than 1 year old to more than 70, with a male to female ratio of 2:1. The peak age for the development of calcium oxalate stones was between 50–60 years [8]. The risk of stone formation is generally high in men; however it is becoming more common in young women. Men are at greatest risk of developing kidney stones with incidence and prevalence rates between 2–4 times that of women which could be due to the larger muscle mass of men as compared to women [9, 10]. This higher rate of occurrence in men than in women can also be due to enhancing capacity of testosterone and inhibiting capacity of oestrogen in stone formation [11]. Also, the increase daily breakdown of the tissues in men could result in increased metabolic waste and a predisposition to stone formation [12]. The other more significant cause may be because of the male urinary tract being more complicated than the female urinary tract [13]. Estrogen may also help to prevent the formation of calcium stones by keeping urine alkaline and raising protective citrate levels [14]. However, recently there are reports of dramatic increase during the period from 1997 to 2002 in the prevalence of stone disease among females and a change from a 1.7:1 to 1.3:1 male to female ratio. The increasing incidence of nephrolithiasis in women might be due to lifestyle associated risk factors, such as obesity [15]. Some reports have described that vegetarians are at lower risk for stone formation in contrast to non-vegetarians [16].

1.2 Prevalence of urolithiasis in Manipur

In Manipur, the situation is not an exception as the incidence of urolithiasis is high. It is commonly believed that almost every family has a member afflicted with this disease. A study in Manipur on a sample of 875 individuals with urolithiasis revealed that the disease was observed to be significantly more common 109 (56.7%) in the age group of 25 to 44 years, and majority 820 (93.7%) of the people consumed fish daily and nearly two-third of the study population consumed only 2-4 glasses of water per day [17]. From hospital records for a period of seven years and three months urolithiasis was found to be the case in 11.6% of all general surgery cases in General Hospital, Imphal [18]. Also, males are more affected. Urolithiasis was also significantly more prevalent among those individuals with history of UTI (50.6%), and the condition was also observed to be more common among those who had a family history of urolithiasis 73 (67%) and among individuals who are more stressed. Among the affected cases the majority of them are Hindus, and few percentage of Tribals and Muslims. In Hindus of Manipur, the cereal food is introduced between five to 7 months of life after a ceremony called “anaprasan” or “chaamba”. The involvement of single cereal diet in the stone formation can be speculated [20]. The occurrence of stones is very low in the affluent class, but very high in the low socioeconomic class.

2. Types of Calculi

Kidney stones are mainly of four types [20]. The stone types are named after its mineral composition. The most common stones are calcium oxalate, struvite, uric acid and cystine stones. These chemicals are part of a person’s normal diet and make up important parts of the body, such as bones and muscles. In Manipur, oxalate and calcium were present in all the stones, followed by few percentages of stone of phosphate and uric acid. Uric acid was present in all renal stones. Calculi can occur in various sites in the urinary tract in the following order of frequency i.e. vesical < renal < ureteral < urethral. In general, the occurrence of calculi is higher in the lower part of the urinary tract in all age groups. Globally, calcium oxalate is considered as the main constituent in the renal calculi. Calcium containing stones, especially calcium oxalate monohydrate (COM), also known as whewellite, calcium oxalate dehydrate (COD), also known as weddellite, and basic calcium phosphate (apatite) are the most commonly occurring stones to an extent of 75-90% followed by magnesium ammonium phosphate (struvite) to an extent of 10-15%, uric acid 3-10% and cystine 0.5-1% [21]. Silicate stones or drug induced stones are very rarely seen, and can be a result of taking certain medications or herbal products and the subsequent build-up of chemicals from those products in the urine [22]. Some of these drugs are loop diuretics, acetzolamide, topiramate, zonisamide, laxatives (when abused), ciprofloxacin, sulfa medications, triamterene, indinavir, ephedrine, guaifenesin, and products containing silica. A less common type of stone is caused by infection in the urinary tract. This type of stone is called struvite or infection stone. Another type of stone namely uric acid stones are a bit less common, and cystine stones are very rare.

3. Current management and treatment of Urolithiasis

The first step in the prevention and treatment of recurrent urolithiasis is to increase the daily fluid intake to at least 2.5 L to 3 L per day [23] along with pain controlling drugs and medications to monitor salts that may increase or reduce formation of stones. Many allopathic agents like thiazide diuretics (hydrochlorothiazide), alkali (potassium citrate), allopurinol, sodium cellulose phosphate (SCP), penicillamine (cuprimine), analgesic (diclophenac sodium), bisphosphonates, potassium phosphate and probiotics (Oxalobacter formigenes) are used in treating stones. Thiazide diuretics (e.g., hydrochlorothiazide, chlorothalidone and indapamide) produce an increase in tubular reabsorption of calcium, which diminishes calciuria, and hence are effective in reducing calciuria and stone recurrence. These drugs also increase positive calcium balance and thereby increase bone mineral density. Alkalis are used to increase the urinary citrate excretion in patients with hypoxtritarria. Allopurinols are used to reduce uric acid synthesis and urinary excretion in patients with hyperuricaemia and hyperuricosuria. Sodium cellulose phosphates (SCP) are used to restore normal calcium excretion by reducing intestinal calcium absorption. SCP may also induce hypermagnesemia leading to increase saturation of CaOx by reducing the complexity of urinary oxalate. Penicillamines are often recommended if drinking more fluids does not control cystine formations. Analgesics are recommended for less painful passage of ureteral stones which are expected to pass spontaneously. They are also useful in controlling recurrent pains associated with urolithiasis. Bisphosphonates are used to decrease calciuria. Potassium phosphates help in increasing serum phosphate, increase urine phosphate and possible increase in urine pyrophosphates. Oxalobacter formigenes and other probiotics help in decreasing oxalate excretion. However, most of these standard pharmaceutical drugs used to prevent and cure urolithiasis are not effective in all cases, costly, quite common recurrences, risks of long term fertility, potential side effects and no guarantee [24].

Small stones are more likely to pass spontaneously than large ones, and distal stones are more likely to pass spontaneously than stones more proximal in the urinary tract. Ureteral stones of less than 4 mm in diameter have a chance of over 80% to pass spontaneously [23]. Most ureteral stones smaller than 5 mm in diameter pass
effects is growing due to their efficiency, low toxicity and absence of side 
stone surgery [31, 32]. Despite these advancements, techniques such 
ureteroscopic extraction have dramatically reduced the role of open 
ureteroscopy, most patients with symptomatic upper tract calculi 
necessitate intervention. Before the advent of lithotripsy and 
and passing on this knowledge orally. Because of prompt and 
indigenous folk remedies to cure various diseases for generations 
local flora. People in such areas have been traditionally using 
positive effect of herbal treatment they have strong faith in their 
Mechanisms of stone formation and treatment, the worldwide 
incidence of urolithiasis is quite high and there is no truly 
satisfactory drug for treatment of renal calculi [35].

4. Role of medicinal plants as antiurolithiatic agents

Of late, there has been a growing resurgence and revival of interest 
in indigenous systems of medicine and traditional herbal remedies, 
which are regarded as quite safe with minimal or no side effects, 
cost effective, readily available and easily affordable [36-39]. 
Medicinal plants have been known for millennia and are highly 
esteeled all over the world as a rich source of therapeutic agents 
for prevention of diseases and ailments [40]. Interest in herbal drugs 
is growing due to their efficiency, low toxicity and absence of side 
effects [41]. People living in the interiors and inaccessible remote 
rural areas have excellent knowledge about medicinal utility of the 
local flora. People in such areas have been traditionally using 
indigenous folk remedies to cure various diseases for generations 
and passing on this knowledge orally. Because of prompt and 
positive effect of herbal treatment they have strong faith in their 
own folk medicinal preparations or crude formulations [38, 41].

4.1 Antiurolithiatic plants of Manipur

The North-East India is a treasure house of vast variety of plant 
resources being a part of the Indo-Burma Biodiversity Hotspot. 
Manipur, which is one of the states in North-East India, is located 
between 23.83° N and 25.68° N latitude and 93.03° E and 94.78° E 
longitudes. It covers a geographical area of 22,327 sq. km of which 
90% are hilly regions largely characterised by dense forests and 
inaccessible terrains, and is a home to 4000 angiospermic plants. 
The state is rich in flora and fauna and falls under the Indo-
Myanmar biodiversity hotspot, one of the 25 global biodiversity 
hotspots acknowledged currently [42]. It is believed that this part of 
India was used as crucial corridor for human migrations including, 
perhaps, the first migrations from Africa towards East Asia and 
Australia more than 40,000 years ago [43]. The use of medicinal plants 
plays a very vital role in the health care of tribal people. These 
primitive people have used plants to cure a variety of ailments, but they keep no records and the information is mainly 
passed on verbally from generation to generation [44].

Based on various documents of medicinal plants used in 
treatment of kidney stones and ailments related to urinary system 
in Manipur by researchers working on this biodiversity rich region 
from 2005 till 2014, it is found that 107 plants, of which one is an 
alu, belonging to 51 different families are used by different ethnic 
communities of Manipur like Meeteis, Muslims and tribals for 
treatment of kidneys stones and related ailments such as urinary 
infections and urinary problems. The plants which are used as 
twurolithiatic agents are reported along with uses and mode of 
uses [17, 45-61]. The complete documented lists of 107 antiurolithiatic plant 
agents are given in Table 1. These plants are traditionally 
used to dissolve kidney stones or to prevent formation of stone. 
From these documents it is observed that plants belonging to 
Asteraceae, Rosaceae, Euphorbiaceae, Malvaceae and 
Cucurbitaceae are mostly used in treatment of kidney stones and 
ailments related to urinary stone and urinary problems. However, 
plants belonging to family Oxalidaceae, Nelumbonaceae, 
Mimosaceae, Magnoliaceae, Myrtaceae, Menispermaceae, 
Linderniaceae, Clusiaceae, Caesalpiniaceae, Cyperaceae, 
Caricaceae, Bromeliaceae, Boraginaceae, Alliaceae, 
Amaryllidaceae, Amaranthaceae, Asclepiadaceae, Urticaceae, 
Plantaginaceae, Santalaceae, Solanaceae, Theaceae, Umbelliferae, 
Ulmaceae, and Pedaliaceae are less reported in the documentations 
for their use as antiurolithiatic agents.

Each tribe in Manipur has its own unique knowledge of using 
plants as medicines, also they have their unique traditional 
medicinal knowledge, which in many cases are different from other 
tribes, and are handed down orally from one generation to another 
since its civilization. The living population of this region has been 
using various medicinal plants for the treatment of stone cases. It 
was also found that different ethnic communities use different 
plants for treatment related to urolithiasis, which indicates the fact 
that their traditional knowledge are unique to themselves. For 
instance, the plant Anneslea fragrans was found to be used only by 
the Khosbu community [52], the Thadou tribe on the other hand uses 
Saccharum officinarum for kidney infections [54] asserting the fact 
that these traditional practices were unique to the communities 
that hold these knowledge, and are passed down from one generation 
to another orally. On the other hand, most of the plants used by 
the Muslims and the Meetei communities of Manipur are common, 
with minor differences in the mode of use, which may be due to 
these communities having a common language as well as more 
closeness in their settlements as compared to the tribes who 
occupied most of the hills with more scattered pattern of 
settlements, and the differences in languages and cultures among 
the different tribes.

The documented works reported in this review on antiurolithiatic 
medicinal plants from Manipur beginning from 2005 till date is 
less than that of just 10 tribes of Manipur along with that of the 
Meeteis and the Muslims, whereas Manipur is comprised of about 
34 tribes. It is, thus probable that the lists of the plants use as 
antiurolithiatic will add up in the following years, since the
ethnomedicinal knowledge of majority of the tribes have not been available in the documented form till now. Moreover, most of these medicinally claimed plants are yet to be subjected to phytochemical analysis for their efficacy except a few of them. In India, many medicinal plants are reported for use in urolithiasis, however their usefulness has not been scientifically assessed except in few cases. The simple extracts (infusions) from medicinal plants which have diuretic effect seem to be the most available for preparation and usage. Most of all, they are used only with purpose to increase diuresis. Meanwhile, they have ability to change other urine parameters. Out of seventeen medicinal plants from Manipur analysed Cissus adnata, Cuminum cyminum., Eupatorium birmanicum, Hibiscus sabdariffa, Oxalis corniculata, Piper longum and Tamarindus indica significantly prevented crystal formation in urine and exhibit strong antibacterial activity against four urolithiasis inducing microbes. It was also reported that ethanol extracts of Hibiscus sabdariffa, Tamarindus indica and Piper longum showed comparatively the highest efficacies in dissolving the stone. Thus, C. adnata, C. cuminum, E. birmanicum, H. sabdariffa, O. corniculata, P. longum and T. indica showed promising role in prevention and control of urolithiasis [62]. Investigation of the role of ‘varuna’ (Crataeva nurvala) in urinary disorders showed that it has a potent antiseptic property, changes the urine chemistry which would check the growth of the stone and tones up the bladder muscle, thereby facilitating the expulsion of stones [63]. Medicinal plants such as Cuminum cyminum and Eupatorium birmanicum controls urolithiasis even though they render the urine alkaline. Herbal drugs such as Cystone are made from indigenous plants Didymocarpus pedicellata, Saxifraga ligulata, Rubia cordifolia, Cyperus scariosus, Achyranthes aspera, Onosma bracteatum, Vernonia cinerea, Shilajit purified and Hajrul yahood bhasma. Cystone is reported to have a key role in controlling kidney stone formation as the antibacterial activities. ‘Chandraprabha Vati’ is an Ayurvedic formulation used for the treatment of Diabetes and urinary diseases. It is formulated from Commipora wightii, Gomutra silajith[64]. Herbal formulation ‘Trinapanchamool’ consists of five herbal drugs namely Desmostachya bipinnata, Saccharum officinarum, Saccharum nunja, Saccharum spontaneum and Imperata cylindrical and is effective both as a prophylactic in preventing the formation and as a curative in dissolving the pre-formed stones in albino rats [65]. Similarly, other ayurvedic medicine formulated from medicinal plants which are used in the treatment of urolithiasis are Calcurti, Rencare Capsul, Pather ina tablet, Ber Patthar Bhasma. Formulations of these herbal drugs are possible when the uses of such plants are available in documented forms.

5. Conclusion
At present, the traditional health care system which was once used to be the lifeline of the people seems to be in the verge of extinction. The wealth of information preserved as an unwritten medicinal knowledge amongst the ethnic communities seems to be slowly fading and the oral tradition of passing on knowledge from generation to generation is declining. Also, there are many other cases in which the knowledge still remains a secret amongst the tribes. In addition, the general trend towards more dependency on modern way of living leads to diminishing in the age old practice of handling down the traditional medicinal knowledge orally from one generation to another among the tribals and remote people. Moreover, the extensive felling of trees for timber, fuel, practices of shifting cultivation for which vast vegetations have to be cleared, preparation of land for terrace cultivation and uncontrolled human settlement have also threatened the valuable medicinal plants. Further, the ever increasing demand of herbal medicines both in the domestic and international market leads to unauthorized collection, indiscriminate destruction and overexploitation of these resources from wild state. Also, the exploitation of the traditional knowledge by various pharmaceutical companies in the form of patenting, by selling the drugs obtain from indigenous medicinal plants with high price tags, for which the ultimate effects are visible to the poor and remote tribes who actually owns the medicinal knowledge is another issue. Thus documentation and preservation of the traditional knowledge are the great challenges of the hour, so that the vast knowledge of the ethnic communities residing in this biodiversity hot spot region of the country can still be preserved for future research in pharmaceuticals and drug discovery, without compromising the contributions and prospects of benefit sharing to the ethnic communities who have played a tremendous role in shaping modern drug formulations. The present review on documentations of the complete information of plants used as antiurolithiatic agents in Manipur will help in guiding the researcher to identify new source of drugs for this ever prevailing human ailment. These ethnomedicinal knowledge if properly safeguarded, will serve as a novel irreplaceable resource for isolation and synthesis of the most reliable drugs for urolithiasis which is still a long overdue.
